April 15, 2014

Dear Parent/Guardian,

Santa Clara County continues to have one of the highest rates of tuberculosis (TB) in the United States. TB is a bacterial infection spread through the air and can affect the lungs, brain, bones, or any part of the body. Children can become infected when traveling, from household members, family, or visitors who are infected. Children exposed to someone with TB have a very high risk of developing active TB. If diagnosed early, TB is treatable and preventable.

Santa Clara County has required mandatory tuberculosis (TB) testing for students enrolling in school. However, effective June 1, 2014, students enrolling into school will be required to undergo TB testing ONLY if their healthcare provider identifies a risk factor for TB exposure. Prior to school enrollment children will be required to have their healthcare provider complete the Santa Clara County Public Health Department Risk Assessment for School Entry form which is attached. Take this form to your provider to complete and return to your child’s school. This requirement applies to students attending both public and private schools in Santa Clara County and is based on the authority given the Santa Clara County Health Officer under the California Health and Safety Code, Section 121515.

This new policy will decrease unnecessary testing and allow healthcare providers to ensure that children who have TB infection are evaluated and treated promptly.

Thank you for helping us protect the health of your children.

Sincerely,

Teeb Al-Samarrai, MD
Tuberculosis Controller

Board of Supervisors: Mike Wasserman, Cindy Chavez, Dave Cortese, Ken Yeager, S. Joseph Simitian
County Executive: Jeffrey V. Smith
Santa Clara County Public Health Department
Tuberculosis (TB) Risk Assessment for School Entry

This form must be completed by a licensed health professional in the U.S. and returned to the child’s school.

1. Was your child born in, resided, or traveled (for more than one month) to a country with an elevated rate of TB*?  
   - Yes  
   - No

2. Has your child been in close contact to anyone with tuberculosis (TB) disease in their lifetime?  
   - Yes  
   - No

3. Is your child immunosuppressed; current, or planned? (e.g., due to HIV infection, organ transplant, treatment with TNF-alpha antagonist or high-dose systemic steroids (e.g. prednisone ≥ 15 mg/day for ≥ 2 weeks).  
   - Yes  
   - No

*Most countries other than the U.S., Canada, Australia, New Zealand, or a country in western or northern Europe. This does not include tourist travel for <1 month (i.e., travel that does not involve visiting family or friends, or involve significant contact with the local population).

If YES, to any of the above questions, the child has an increased risk of TB and should have a TB blood test (IGRA, i.e. QuantIFERON or T-SPOT.TB) or a tuberculin skin test (TST) unless there is either 1) a documented prior positive IGRA or TST performed in the U.S. or 2) no new risk factors since last documented negative IGRA (performed at age ≥2 years in the U.S.) or TST (performed at age ≥6 months in the U.S.).

All children with a current or prior positive IGRA/TST result must have a medical evaluation, including a chest x-ray (CXR; posterior-anterior and lateral for children <5 years old is recommended). CXR is not required for children with documented prior treatment for TB disease, documented prior treatment for latent TB infection, or BCG-vaccinated children who have a positive TST and negative IGRA. If there are no symptoms or signs of TB disease and the CXR is normal, the child should be treated for latent TB infection (LTBI) to prevent progression to TB disease.

Enter test results for all children with a positive risk assessment:

Please check one of the boxes below and sign:

- Child has no TB symptoms, no risk factors for TB, and does not require a TB test.
- Child has a risk factor, has been evaluated for TB and is free of active TB disease.
- Child has no new risk factors since last negative IGRA/TST and has no symptoms.

Testing Methods
An Interferon Gamma Release Assay (IGRA, i.e., QuantiFERON or T-SPOT.TB) or Mantoux tuberculin skin test (TST) should be used to test those at increased risk. An IGRA can be used in all children ≥ 2 years old and is preferred in BCG-vaccinated children to avoid a false positive TST result. A TST of ≥10mm induration is considered positive. If a child has had contact with someone with active TB disease (yes to question 2 on reverse), or the child is immunosuppressed, then TST ≥5 mm is considered positive. If a BCG-vaccinated child has a positive TST, and an IGRA is subsequently performed and is negative, testing is considered negative unless the child was exposed to someone with TB disease or is immunosuppressed. For immunosuppressed children, screening should be performed by CXR in addition to a TST/IGRA (consider doing both) and symptom review. TB screening can be falsely negative within 8 weeks after exposure, so are best obtained 8 weeks after last exposure.

Evaluation of Children with Positive TB Tests
• All children with a positive IGRA/TST result must have a medical evaluation, including a CXR (posterior-anterior and lateral is recommended for children <5 years old). A CXR is not required for a positive TST with negative IGRA in a BCG-vaccinated child, or if the child has documentation of prior treatment for TB disease or treatment for latent TB infection.
• For children with TB symptoms (e.g., cough for >2-3 weeks, shortness of breath, hemoptysis, fever, weight loss, night sweats) or an abnormal CXR consistent with active TB disease, report to the County of Santa Clara Public Health Department TB Program within one day. The child will need to be evaluated for TB disease with sputum AFB smears/cultures and nucleic acid amplification testing. A negative TST or IGRA does not rule out active TB disease in a patient with symptoms or signs of TB disease. The child cannot enter school unless active TB disease has been excluded or treatment has been initiated.
• If there are no symptoms or signs of TB disease and the CXR is normal, the child should be treated for latent TB infection (LTBI). Do not treat for LTBI until active TB disease has been excluded.
• Short-course regimens (rifampin daily for four months or 12-dose weekly isoniazid/rifapentine) are preferred (except in persons for whom there is a contraindication, such as a drug interaction or contact to a person with drug-resistant TB) due to similar efficacy and higher treatment completion rates as compared with 9 months of daily isoniazid.

Treatment Regimens for Latent TB Infection
• Rifampin 15 - 20 mg/kg (max. 600 mg) daily for 4 months
• 12-dose Weekly Isoniazid/Rifapentine (3HP) Regimen:
  • Isoniazid
    2-11 years old: 25 mg/kg rounded up to nearest 50 or 100 mg (max. 900 mg)
    ≥ 12 years old: 15 mg/kg rounded up to nearest 50 or 100 mg (max. 900 mg)
  • Rifapentine
    10.0-14.0 kg: 300 mg
    14.1-25.0 kg: 450 mg
    25.1-32.0 kg: 600 mg
    32.1-50.0 kg: 750 mg
    >50 kg: 900 mg
  • Vitamin B6 50 mg weekly
• Isoniazid 10 mg/kg (range, 10-15 mg/kg; max. 300 mg) daily for 9 months. Recommended pyridoxine dosage is 25 mg for school-aged children (or 1-2 mg/kg/day).

Fee: sliding scale, accept adult and children.

Neighborhood Health Clinic
Washington School, 100 Oak Street (Clinic located on Edwards St. behind the school), San Jose, CA 95110; 408-295-0980;
Appointment or walk-in;
M-F: 8am-4:30pm (closed 12pm-1pm for lunch break);
Visit Fee: $25.00 for everyone;
No X-rays at site, refers chest X-rays to Just X-Ray.

St. James Health Center
55 E. Julian St., San Jose, CA 95112; 408-918-2600, by appointment only, 408-918-2641
M-F 8:30am-5:00pm;
TST: Accepts insurance, Medical, or fee: $15; Accepts adults and children; No X-rays at site, refers chest X-rays to JXR and VMC.

San Jose Foothill Family Community Clinic
2880 Story Road, San Jose, 95127; 408-729-4282;
M-F 8:00am-8:00pm, S-S 8:00am-5:00pm;
Walk-in: 8am-11am, 1pm-3pm (M, T, W, F, S); Prefer appointment;
Accept insurance, sliding fee scale, or $35.00 for uninsured;
Accept adult and children;
No X-rays at site, refers chest X-rays to JXR and VMC.

Indian Health Center
1333 Meridian Ave, San Jose, CA 95125; 408-445-3400;
M-F 8:00am-5:00pm New patients need to register prior to appointment for TST;
Fee: $30.00 Accepts adult and children;
No X-rays at site, refers to other sites for X-rays.

Franklin McKinley School Center
645 Wool Creek Dr., San Jose, CA 95112; 408-283-6051;
Call for appointment; $25 for pts without insurance;
No X-rays at site

Overfelt Neighborhood Health Clinic
1835 Cunningham Ave, San Jose, 95122; 408-347-5988;
Mon-Wed & Fri 8:00am-4:30 pm (closed 12pm-1pm for lunch);
Immunizations/TST: Tuesday 8:00-10:30.

Mar Monte Community Clinic
2470 Alvin Ave. Ste 60, San Jose, CA 95121
Call for appointment: 408-274-7100; Sliding fee scale
Mon, Tue, Thurs., Fri 8:45am-5:00pm, W 8:45am-6:30pm, Sat 8:45am-1:00pm.
No X-rays at site - refer to VMC for CXR.

Family Medicine Center at O’Connor
455 O’Connor Drive, Suite 200, San Jose, 95128; 408-283-7676;
Mon-Fri 8:30am-5:30pm

Revised 6/6/14
What is Tuberculosis?

Tuberculosis (TB) is an ancient disease that is still affects many people in Santa Clara County. TB is caused by the bacteria *Mycobacterium tuberculosis* and is spread from person to person through the air when an individual with TB coughs, sneezes, or speaks. Individuals who breathe in infected droplets become infected with TB and are at risk for developing TB disease.

People who have TB can have two types of infection:

1. Latent or “silent” TB infection: Individuals with latent TB infection (LTBI) have a small amount of TB in their bodies that their immune system keeps under control. They do not have symptoms, are not contagious and may remain that way for years. Treatment of LTBI can prevent TB disease in the future.

2. Active TB disease: Occurs when TB bacteria multiply and a person develops symptoms such as cough, fever, or weight loss. They can also spread disease to others. Active TB disease can develop in people with LTBI when the immune system is weakened by stress or a medical illness, such as diabetes, cancer, kidney disease, or HIV. Certain behaviors, such as smoking, also increase an individual’s risk for developing TB disease.

TB usually affects the lungs, but can also affect any part of the body such as lymph nodes, bones and joints, kidneys, intestines, and the brain. TB can be treated but if untreated, can be fatal.

TB in Santa Clara County

There were 181 cases of TB in Santa Clara County (SCC) in 2013 which is an increase from the downward trend through 2012 (N=176). This represents a rate of 9.8 cases per 100,000 residents in Santa Clara County which is higher than the rate in California overall of 5.7 per 100,000 people and more than three times the United States rate of 3.0 per 100,000 people.

Who’s at risk for TB infection and developing active TB disease?

People who were born in or travel to countries with high TB rates are at the highest risk for being exposed to TB. For people with LTBI, certain medical conditions such as diabetes, end stage renal and behaviors increase the risk of progression from latent TB infection to active TB disease.

- People with LTBI and diabetes are three times more likely to develop active TB disease than non-diabetics with latent TB infection.
• 20% (36/181) of Santa Clara County TB cases identified in 2013 also had diabetes\textsuperscript{1}.

• People with LTBI who smoke are 2.5 times more likely to develop active TB disease than non-smokers with LTBI\textsuperscript{6}. Studies have shown that people with LTBI who are exposed to secondhand smoke are also more likely to develop active TB disease compared to those with TB infection not exposed to second hand smoke\textsuperscript{10}.

• According to a World Health Organization review, people with heavy alcohol use are almost 3 times more likely to develop active TB disease than those who do not drink alcohol\textsuperscript{11}.

• Other risk factors that increase the likelihood of progression from LTBI to active TB disease include HIV or other immune-compromising conditions, chronic kidney disease, or immunosuppressant medications such as TNF-α inhibitors or steroids (Table 1).

Source: California Reportable Disease Information Exchange, 2013;
\textsuperscript{*}163/181 (90%) of TB cases had documented screening for HIV infection

Who had TB in Santa Clara County in 2013?

In 2013, the majority of TB cases (58%) were among people between 25 and 64 years of age. Children and young adults between 0 to 24 years of age accounted for 10% of TB cases. Almost 32% of people diagnosed with TB were older than 65 years of age\textsuperscript{1}. The majority of SCC TB cases are of Asian or Hispanic race/ethnicity. Although the TB case rate among Asians in Santa Clara County has been trending downward from a peak of 37 per 100,000 people in 2007\textsuperscript{12}, it remains eight times the overall rate of TB in the US at 24.7 per 100,000 people in Santa Clara County. This rate is higher among foreign-born residents from certain Asian countries (Figure 1).

In 2013, 91% of active TB cases were in foreign-born residents, primarily from the following countries: Vietnam, Philippines, India, Mexico and China. The majority (67%) of foreign-born
residents who developed active TB disease had lived in the United States for more than 5 years\textsuperscript{1}.

**Figure 1: Tuberculosis case rates by country of origin, Santa Clara County, 2013\textsuperscript{1}**

![Tuberculosis case rates by country of origin, Santa Clara County, 2013](image)

**How does TB make us sick?**

When TB affects the lungs, it is called pulmonary TB and can be spread to others. In 2013, almost three quarters (73\%) of TB cases in Santa Clara County had pulmonary TB\textsuperscript{1}.

Five adults with TB died in Santa Clara County, 2 of whom were younger than 64 years of age and 3 were 65 years or older\textsuperscript{2}. No children died of TB in Santa Clara County in 2013\textsuperscript{1}.

**Drug Resistant TB**

TB that is resistant to standard treatment is challenging to treat and can require 2 years of a complicated medication regimen. In 2013, 14\% (21/145) of TB cases in Santa Clara County with known drug sensitivity results were resistant to at least one of the standard TB medications (rifampin, isoniazid, ethambutol, or pyrazinamide). Of those without a prior history of TB, 13\% (17/135) were resistant to isoniazid\textsuperscript{1}, which was higher than the national average in 2012 (8.9\%)\textsuperscript{5}. Multi-drug resistant TB, which is resistant to both isoniazid and rifampin accounted for 3.0\% of culture confirmed TB cases in Santa Clara County in 2013\textsuperscript{1}. No extensively drug resistant cases were identified in Santa Clara County in 2013.
What should people do to know if they are at risk?

- If someone was born in or travels to countries where TB is endemic such as countries in Asia, Eastern Europe, Africa, or Latin America then they are at risk for having been exposed to TB and should ask their doctor about TB screening.

- If someone has a positive TB test then they should talk to their doctor about getting treated for latent TB infection in order to prevent the development of active TB disease.

- Treatment of latent TB infection is especially important for children, people with diabetes, HIV, people who smoke, a history of smoking, or exposure to tobacco smoke, chronic kidney disease, or who might be treated with immunosuppressant medications (e.g. prednisone, TNF-α inhibitors).
